Heap Sort Algorithm

(<https://srv.carbonads.net/ads/click/x/GTND42QYCWADCK7NFT7LY>
se! ADS VIA CARBON
([HTTP://CARBONADS.NET/?UTM_SOURCE=WWWPROGRAMIZCOM&UTM_MEDIUM=AD_VIA_LINK&UTM_CAMPAIGN=IN_UNIT&UTM_TERM=CARBON](http://CARBONADS.NET/?UTM_SOURCE=WWWPROGRAMIZCOM&UTM_MEDIUM=AD_VIA_LINK&UTM_CAMPAIGN=IN_UNIT&UTM_TERM=CARBON))

Heap Sort is a popular and efficient sorting algorithm in computer programming. Learning how to write the heap sort algorithm requires knowledge of two types of data structures - arrays and trees.

The initial set of numbers that we want to sort is stored in an array e.g.

[10, 3, 76, 34, 23, 32] and after sorting, we get a sorted array

[3, 10, 23, 32, 34, 76]

Heap sort works by visualizing the elements of the array as a special kind of complete binary tree called heap.

What is a complete Binary Tree?

Binary Tree

A binary tree is a tree data structure in which each parent node can have at most two children

Thank you for printing our content at www.domain-name.com. Please check back soon for new contents.

www.domain-name.com

In the above image, each element has at most two children.

Full Binary Tree

A full Binary tree is a special type of binary tree in which every parent node has either two or no children.

Complete binary tree

A complete binary tree is just like a full binary tree, but with two major differences

1. Every level must be completely filled
2. All the leaf elements must lean towards the left.
3. The last leaf element might not have a right sibling i.e. a complete binary tree doesn't have to be a full binary tree.

How to create a complete binary tree from an unsorted list (array)?

- Select first element of the list to be the root node. (First level - 1 element)
- Put the second element as a left child of the root node and the third element as a right child. (Second level - 2 elements)
- Put next two elements as children of left node of second level. Again, put the next two elements as children of right node of second level (3rd level - 4 elements).
- Keep repeating till you reach the last element.

www.domain-name.com

Complete binary tree has an interesting property that we can use to find the children and parents of any node.

If the index of any element in the array is i , the element in the index $2i+1$ will become the left child and element in $2i+2$ index will become the right child. Also, the parent of any element at index i is given by the lower bound of $(i-1)/2$.

Let's test it out,

Thank you for printing our content at www.domain-name.com. Please check back soon for new contents.

www.domain-name.com

```
= element in 1 index
= 12

Right child of 1
= element in (2*0+2) index
= element in 2 index
= 9

Similarly,
Left child of 12 (index 1)
= element in (2*1+1) index
= element in 3 index
= 5

Right child of 12
= element in (2*1+2) index
= element in 4 index
= 6
```

Let us also confirm that the rules holds for finding parent of any node

```
Parent of 9 (position 2)
= (2-1)/2
= ½
= 0.5
~ 0 index
= 1

Parent of 12 (position 1)
= (1-1)/2
= 0 index
= 1
```

Understanding this mapping of array indexes to tree positions is critical to understanding how the Heap Data Structure works and how it is used to implement Heap Sort.

What is Heap Data Structure ?

Heap is a special tree-based data structure. A binary tree is said to follow a heap data structure if

Thank you for printing our content at www.domain-name.com. Please check back soon for new contents.

www.domain-name.com

All nodes in the tree follow the property that they are greater than their children i.e. the largest element is at the root and both its children and smaller than the root and so on. Such a heap is called a max-heap. If instead all nodes are smaller than their children, it is called a min-heap

Following example diagram shows Max-Heap and Min-Heap.

How to “heapify” a tree

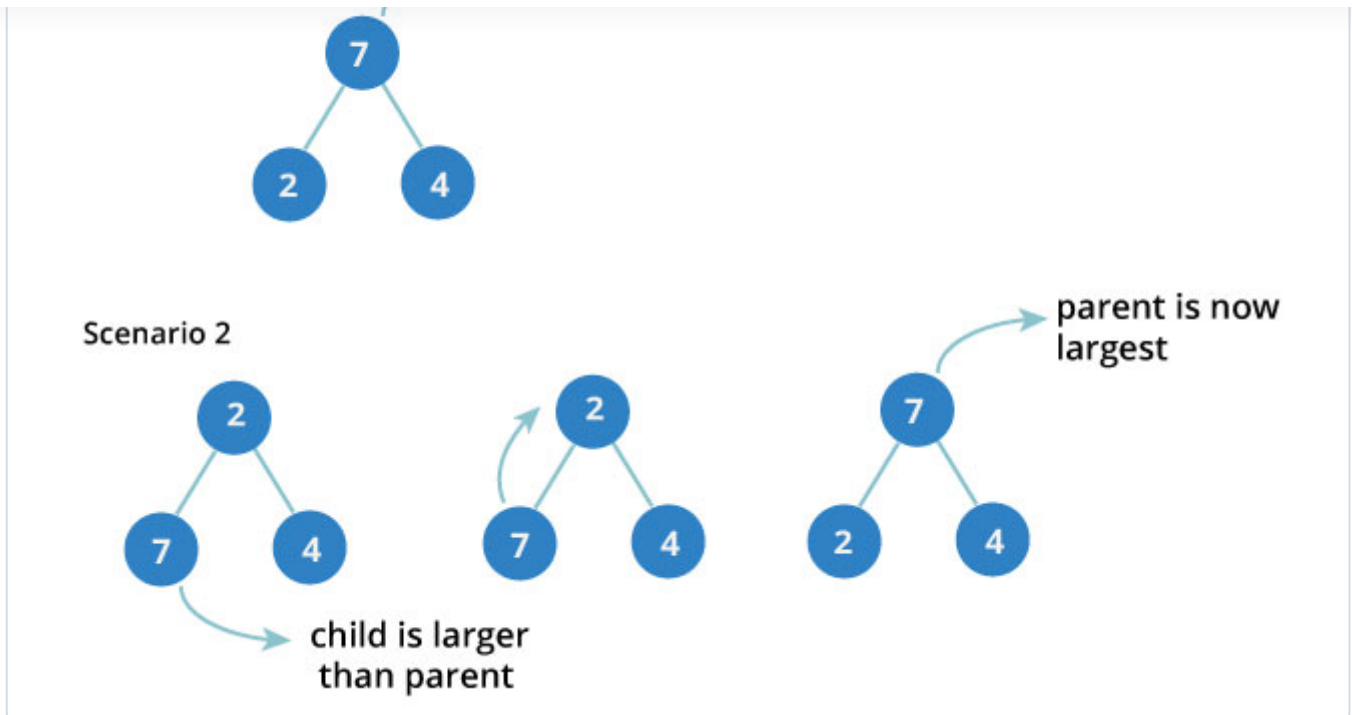

Starting from a complete binary tree, we can modify it to become a Max-Heap by running a function called heapify on all the non-leaf elements of the heap.

Since heapify uses recursion, it can be difficult to grasp. So let's first think about how you would heapify a tree with just three elements.

```
heapify(array)
    Root = array[0]
    Largest = largest( array[0] , array [2*0 + 1], array[2*0+2])
    if(Root != Largest)
        Swap(Root, Largest)
```

Thank you for printing our content at www.domain-name.com. Please check back soon for new contents.

www.domain-name.com

The example above shows two scenarios - one in which the root is the largest element and we don't need to do anything. And another in which root had larger element as a child and we needed to swap to maintain max-heap property.

If you're worked with recursive algorithms before, you've probably identified that this must be the base case.

Now let's think of another scenario in which there are more than one levels.

Thank you for printing our content at www.domain-name.com. Please check back soon for new contents.

www.domain-name.com

The top element isn't a max-heap but all the sub-trees are max-heaps.

To maintain the max-heap property for the entire tree, we will have to keep pushing 2 downwards until it reaches its correct position.

Thank you for printing our content at www.domain-name.com. Please check back soon for new contents.

www.domain-name.com

Thus, to maintain the max-heap property in a tree where both sub-trees are max-heaps, we need to run heapify on the root element repeatedly until it is larger than its children or it becomes a leaf node.

Thank you for printing our content at www.domain-name.com. Please check back soon for new contents.

www.domain-name.com

```
void heapify(int arr[], int n, int i)
{
    int largest = i;
    int l = 2*i + 1;
    int r = 2*i + 2;

    if (l < n && arr[l] > arr[largest])
        largest = l;

    if (r < n && arr[r] > arr[largest])
        largest = r;

    if (largest != i)
    {
        swap(arr[i], arr[largest]);

        // Recursively heapify the affected sub-tree
        heapify(arr, n, largest);
    }
}
```

This function works for both the base case and for a tree of any size. We can thus move the root element to the correct position to maintain the max-heap status for any tree size as long as the sub-trees are max-heaps.

Build max-heap

To build a max-heap from any tree, we can thus start heapifying each sub-tree from the bottom up and end up with a max-heap after the function is applied on all the elements including the root element.

In the case of complete tree, the first index of non-leaf node is given by

$n/2 - 1$. All other nodes after that are leaf-nodes and thus don't need to be heapified.

So, we can build a maximum heap as

```
// Build heap (rearrange array)
for (int i = n / 2 - 1; i >= 0; i--)
    heapify(arr, n, i);
```

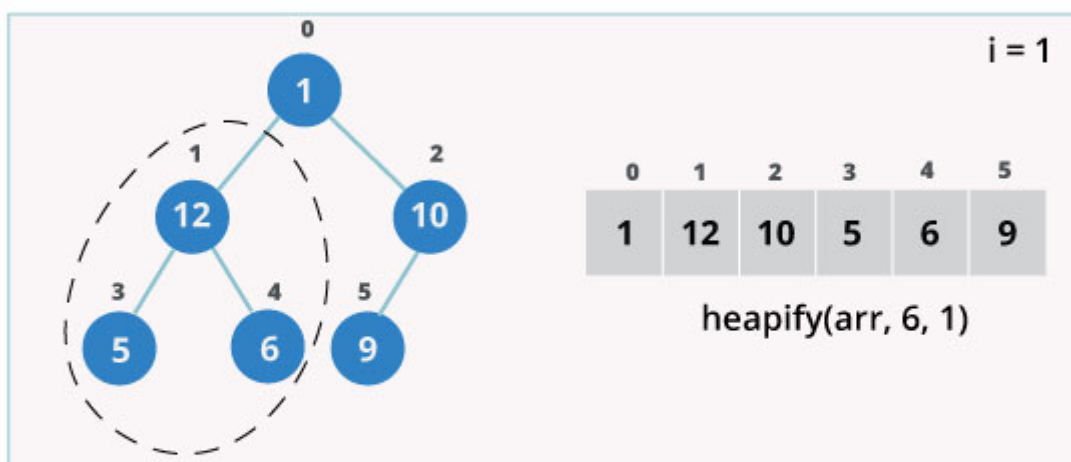

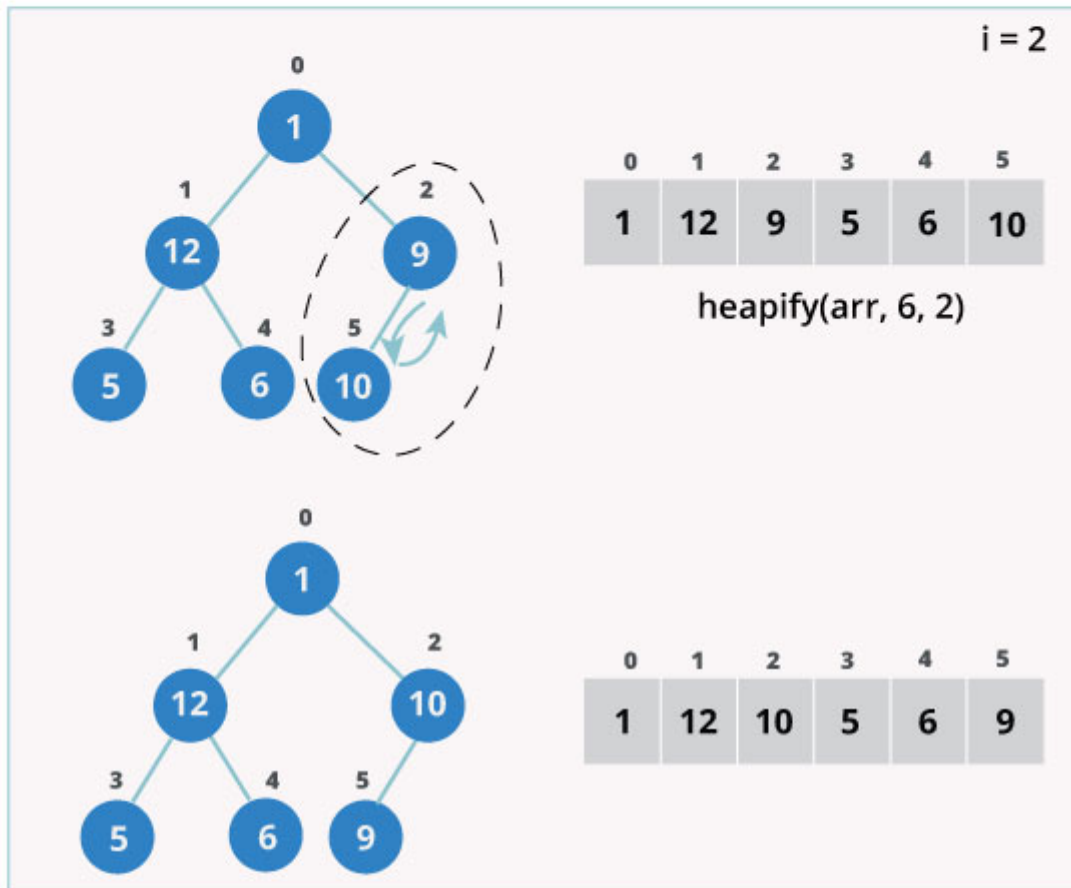

Thank you for printing our content at www.domain-name.com. Please check back soon for new contents.

www.domain-name.com

$$n = 6$$

$$i = \frac{6}{2} - 1$$

$$= 2 \rightarrow 0$$

Thank you for printing our content at www.domain-name.com. Please check back soon for new contents.

www.domain-name.com

As shown in the above diagram, we start by heapifying the lowest smallest trees and gradually move up until we reach the root element.

If you've understood everything till here, congratulations, you are on your way to mastering the Heap sort.

Procedures to follow for Heapsort

1. Since the tree satisfies Max-Heap property, then the largest item is stored at the root node.
2. Remove the root element and put it at the end of the array (nth position). Put the last item of the tree (heap) at the vacant place.

4. The process is repeated until all the items of the list is sorted.

The code below shows the operation.

```
for (int i=n-1; i>=0; i--)
{
    // Move current root to end
    swap(arr[0], arr[i]);

    // call max heapify on the reduced heap
    heapify(arr, i, 0);
}
```

Performance

Heap Sort has $O(n \log n)$ time complexities for all the cases (best case, average case and worst case).

Thank you for printing our content at www.domain-name.com. Please check back soon for new contents.

www.domain-name.com

As we have seen earlier, to fully heapify an element whose subtrees are already max-heaps, we need to keep comparing the element with its left and right children and pushing it downwards until it reaches a point where both its children are smaller than it.

In the worst case scenario, we will need to move an element from the root to the leaf node making a multiple of $\log(n)$ comparisons and swaps.

During the build_max_heap stage, we do that for $n/2$ elements so the worst case complexity of the build_heap step is $n/2 * \log(n) \sim n \log n$.

During the sorting step, we exchange the root element with the last element and heapify the root element. For each element, this again takes $\log n$ worst time because we might have to bring the element all the way from the root to the leaf. Since we repeat this n times, the heap_sort step is also $n \log n$.

Also since the build_max_heap and heap_sort steps are executed one after another, the algorithmic complexity is not multiplied and it remains in the order of $n \log n$.

Also it performs sorting in $O(1)$ space complexity. Comparing with Quick Sort, it has better worst case $(O(n \log n))$. Quick Sort has complexity $O(n^2)$ for worst case. But in other cases, Quick Sort is fast. Introsort is an alternative to heapsort that combines quicksort and heapsort to retain advantages of both: worst case speed of heapsort and average speed of quicksort.

Application of Heap Sort

Systems concerned with security and embedded system such as Linux Kernel uses Heap Sort because of the $O(n \log n)$ upper bound on Heapsort's running time and constant $O(1)$ upper bound on its auxiliary storage.

Although Heap Sort has $O(n \log n)$ time complexity even for worst case, it doesn't have more applications (compared to other sorting algorithms like Quick Sort, Merge Sort). However, its underlying data structure, heap, can be

Thank you for printing our content at www.domain-name.com. Please check back soon for new contents.

Priority Queues.

Heap Sort Implementation in different Programming Languages

C++ Implementation

```
// C++ program for implementation of Heap Sort
#include <iostream>
using namespace std;

void heapify(int arr[], int n, int i)
{
    // Find largest among root, left child and right child
    int largest = i;
    int l = 2*i + 1;
    int r = 2*i + 2;

    if (l < n && arr[l] > arr[largest])
        largest = l;

    if (r < n && arr[r] > arr[largest])
        largest = r;

    // Swap and continue heapifying if root is not largest
    if (largest != i)
    {
        swap(arr[i], arr[largest]);
        heapify(arr, n, largest);
    }
}

// main function to do heap sort
void heapSort(int arr[], int n)
{
    // Build max heap
}
```

Java program for implementation of Heap Sort
